INTRODUCTION

Oral tablets are the most widely used dosage form because of its convenience in terms of self-administration, compactness, and ease in manufacturing. However, geriatric and pediatric patients experience difficulty in swallowing conventional tablets, which leads to poor patient compliance. To overcome this weakness, scientists have developed innovative drug delivery systems known as fast dissolving tablets. Alternatively, tablets were first prepared and later exposed to vacuum. The formulations were evaluated for weight variation, hardness, friability, drug content, wetting time, and in vitro dissolution. All the formulations showed low weight variation with dispersion time less than 55 s and rapid in vitro dissolution. Sublimation of camphor from tablets resulted in superior tablets as compared with the tablets prepared from granules that were exposed to vacuum. The results revealed that the tablets containing the subliming agent had a good dissolution profile. The drug content of all the formulations was within the acceptable limits of the United States Pharmacopoeia XXVII. The optimized formulation showed good release profile with maximum drug being released at all time intervals. It was concluded that fast dissolving tablets with improved naproxen sodium dissolution could be prepared by sublimation of tablets containing a suitable subliming agent. This work helped in understanding the effect of formulation processing variables especially the subliming agent on the drug release profile.

Key words: Camphor, crosscarmellose sodium, naproxen sodium, orodispensible

Formulation and evaluation of naproxen sodium orodispensible tablets – A sublimation technique

The rational of this investigation was to develop fast dissolving tablets of naproxen sodium using camphor as a subliming agent. Orodispensible tablets of naproxen sodium were prepared by the wet granulation technique using camphor as a subliming agent and sodium starch glycolate together with crosscarmellose sodium as superdisintegrants. Camphor was sublimed from the granules by exposing the granules to vacuum. The porous granules were then compressed into tablets. Alternatively, tablets were first prepared and later exposed to vacuum. The formulations were evaluated for weight variation, hardness, friability, drug content, wetting time, and in vitro dissolution. All the formulations showed low weight variation with dispersion time less than 55 s and rapid in vitro dissolution. Sublimation of camphor from tablets resulted in superior tablets as compared with the tablets prepared from granules that were exposed to vacuum. The results revealed that the tablets containing the subliming agent had a good dissolution profile. The drug content of all the formulations was within the acceptable limits of the United States Pharmacopoeia XXVII. The optimized formulation showed good release profile with maximum drug being released at all time intervals. It was concluded that fast dissolving tablets with improved naproxen sodium dissolution could be prepared by sublimation of tablets containing a suitable subliming agent. This work helped in understanding the effect of formulation processing variables especially the subliming agent on the drug release profile.

Naproxen sodium, [(+)-(S)-2-(6-methoxynaphthalen-2-yl) propanoic acid], a nonsteroidal anti-inflammatory drug (NSAID), has been indicated for various painful indications and proved as effective as other NSAIDs with lower indications of gastro-intestinal adverse effects and thus, resulted in a greater compliance with treatment. Naproxen sodium is practically insoluble. For poorly soluble orally administered drugs, the rate of absorption is often controlled by the rate of dissolution. Clear naproxen sodium-loaded soft capsules have been prepared to accelerate the absorption. The rate of dissolution can be increased by increasing the surface area of available drug by various methods.
(micronization, complexation, and solid dispersion). The dissolution of a drug can also be influenced by disintegration time of the tablets. Faster disintegration of tablets delivers a fine suspension of drug particles resulting in a higher surface area and faster dissolution. In the present study, an attempt was made to develop mouth dissolving tablets of naproxen sodium and to investigate the effect of the subliming agent on the release profile of the drug.

MATERIALS AND METHODS

Naproxen sodium (Tablets India Ltd, Chennai, India), croscarmellose sodium, sodium starch glycolate, and Aspartame (Ranbaxy, New Delhi, India). Crospovidone (Concertina Pharma Pvt., Ltd, Hyderabad, India). Camphor, sodium saccharin, mannitol, polyvinyl pyrrolidone (PVP), talc, and magnesium stearate were purchased from S.D. Fine Chemicals, Mumbai, India.

Method

Formulation of orodispersible tablets of naproxen sodium

The adequate number of naproxen sodium orodispersible tablets were prepared using the subliming agent, camphor, sodium starch glycolate, and croscarmellose sodium as superdisintegrants, mannitol as a diluent, sodium saccharin as a sweetening agent, alcoholic solution of PVP (10%w/v) as binder and magnesium stearate with talc as a flow promoter. The composition of the each batch is shown in [Table 1]. The raw materials were passed through a 100-mesh screen prior to mixing. The drug and other ingredients were mixed together, and a sufficient quantity of alcoholic solution of PVP (10%w/v) was added and mixed to form a coherent mass. The wet mass was granulated using sieve no. 12 and regranulated after drying through sieve no. 16. Granules of the formulations containing either of the superdisintegrants but without camphor (F1 or F2) were dried in a tray dryer (Shree Bhagwati Pharma Machinery Company, Gujarat, India) at 60°C for 30 min resulting in localized drying. Other granular formulations (F3 to F6) contained a subliming agent and were dried by the vacuum drying technique in temperature 20-22°C for 8 h. The final moisture content of the granules was found to be between 3 and 4%, which was determined using an IR moisture balance. During drying, the camphor sublimed from the formulations containing either of the superdisintegrants, mannitol q.s. sodium saccharin, mannitol, polyvinyl pyrrolidone (PVP), talc, and magnesium stearate were purchased from S.D. Fine Chemicals, Mumbai, India.

Evaluation of formulated tablets

Hardness 

The crushing strength of the tablets was measured using a Monsanto hardness tester. Three tablets from each formulation batch were tested randomly and the average reading noted.

*All the quantities expressed in %. All batches contain 10% polyvinylpyrrolidone in ethyl alcohol as a binder and 2% talc and 1% magnesium stearate. Camphor was sublimed from granules in batches F3 to F5 and from tablets in batch F6.

Friability

Twenty tablets were weighed and placed in a friabilator (Riche-Rich pharma, Bangalore). Twenty preweighed tablets were rotated at 25 rpm for 4 min. The tablets were then dedusted and reweighed and the percentage of weight loss was calculated. The percentage friability of the tablets was measured as per the following formula:

\[
\text{Percentage friability} = \left( \frac{\text{Initial weight} - \text{Final weight}}{\text{Initial weight}} \right) \times 100
\]

Weight variation

Randomly, 20 tablets were selected after compression and the mean weight was determined. None of the tablets deviated from the average weight by more than ±7.5% (USPXX).

Drug content

Twenty tablets were weighed and powdered. An amount of the powder equivalent to 100 mg of naproxen sodium was dissolved in 100 m of pH 7.4 phosphate buffer, filtered, diluted suitably and analyzed for drug content at 230 nm using UV-Visible spectrophotometer (Elico SL-164, India).

In vitro dispersion time

In vitro dispersion time was measured by dropping a tablet in a 10 ml measuring cylinder containing 6 ml of buffer solution simulating saliva fluid with reference to Indian pharmacopeial standard (pH 7.4).

Dissolution study

In vitro release of naproxen sodium from tablets was monitored by using 900 m of SIF (USP phosphate buffer solution, pH 7.4) at 37±0.5°C and 75 rpm using programmable dissolution tester [Lab India (model: Disso-2000), India]. 5 ml aliquots were withdrawn at 1 min time intervals and were replenished immediately with the same volume of fresh buffer medium. Aliquots, following suitable dilutions, were assayed spectrophotometrically at 230 nm.

Thickness

Thickness of tablet was determined by using dial caliper (Mitutoya, Model CD-6 CS, Japan).
Wetting time\(^{(17)}\)

A piece of tissue paper (12 cm × 10.75 cm) folded twice was placed in a Petri dish (Internal Diameter = 9 cm) containing 9 m of buffer solution simulating saliva pH 7.4. A tablet was placed on the paper and the time taken for complete wetting was noted. Three tablets from each formulation were randomly selected and the average wetting time was noted. The results are tabulated in Table 2.

RESULTS AND DISCUSSION

Water insoluble diluents such as microcrystalline cellulose and dicalcium phosphate were omitted from the study as they are expected to cause an unacceptable feeling of grittiness in the mouth. Among the soluble diluents, mannitol was selected as a diluent considering its advantages in terms of easy availability and negative heat of dissolution. Table 2 shows that all the formulated tablets exhibited low weight variation. Addition of a subliming agent had no pronounced effect on hardness and increased friability of the tablets. The wetting time, \textit{in vitro} dispersion time of the tablets were also considerably reduced in tablets containing camphor [Table 2].

The drug content of all the formulations was found to be between 97.4 and 99.1% which was within the acceptable limits as per USPXXVII. The batches F3 and F5 were prepared using camphor at different concentrations to study its effect on disintegration time. The sublimation time (0.5-8 h) depended on the amount of camphor present initially (0%, 5%, or 10%). Batch F5, containing 10% camphor, showed the least disintegrating time. The results shown in Table 2 indicate that concentration-dependent disintegration was observed in batches prepared using camphor as a subliming agent. The porous structure is responsible for faster water uptake; hence, it facilitates wicking action of Crospovidone in bringing about faster disintegration. It is worthwhile to note that as the concentration of camphor increased, the wetting decreased. Tablets with lower friability (≤0.5%) may not break during handling on machines and/or shipping. The use of a sublimation agent resulted in increased friability probably due to increased porosity. It was decided to incorporate colloidal silicon dioxide, extragranularly, at a level of 1% to decrease the friability of the tablets (batches F5 and F6). Addition of colloidal silicon dioxide resulted in appreciable decrease in friability and marginal decrease in disintegration time. Colloidal silicon dioxide helps to restore the bonding properties of the excipients. In the first few attempts (F1–F5), sublimation of camphor was performed from granules prior to compression into tablets. Batches F1 to F5 showed good mechanical integrity, but the disintegration time was a little longer than the arbitrarily chosen value of less than 50 s. In Batch F6, sublimation was performed after compression rather than directly from granules. The results shown in Table 2 reveal that sublimation of camphor from tablets resulted in faster disintegration. The compaction process might have caused breakage of porous granules and subsequent reduction in porosity. The low value of wetting time and disintegration time indicate that the porosity of tablets of batch F6 would be greater than batches F1 to F5. The granules required 4 h of vacuum drying, whereas the tablets required 8 h of vacuum drying. The longer drying time was required in the case of tablets probably because of the decreased surface area and porosity. \textit{In vitro} release studies were carried out using USPXXIII tablet dissolution test apparatus paddle method at 37±1°C, taking 900 m of simulated intestinal fluid (SIF) as dissolution medium. Speed of rotation of the paddle was set at 75 rpm. Aliquots of 5 m were withdrawn after 1, 2, 4, 6, 8, 10 min and analyzed spectrophotometrically at 230 nm. The \textit{in vitro} dissolution profile [Figure 1] indicated faster and maximum drug release from formulation F6. Formulation F6 prepared by direct sublimation of camphor from final tablets showed release 90.12% drug at the end of 10 min when compared to tablets prepared by sublimation of camphor from granules. The rapid drug dissolution might be due to easy breakdown of particles due to porous structure formation after sublimation of camphor and rapid absorption

CONCLUSION

This line of investigation can be concluded that the sublimation method showed better disintegration and drug release. The prepared tablets disintegrate within few seconds without need of water. The vacuum-drying technique would be an effective alternative approach compared with the use of more expensive adjuvants in the formulation of orodispersible tablets.
