Abstract

**Aim:** The aim of this study is to formulate and evaluate zolmitriptan orodispensible tablets using novel excipients. Zolmitriptan is an antimigraine drug used in the treatment of migraine. **Materials and Methods:** In the present investigation, an attempt has been made to enhance the solubility and dissolution rate of zolmitriptan by formulating it as orodispensible tablets were compressed as tablets using superdisintegrants such as croscarmellose sodium and crospovidone. **Results and Discussion:** Rapid release of zolmitriptan from orodispensible tablets was observed which was influenced by the concentration of superdisintegrants. Among the various tablet formulations prepared with superdisintegrants croscarmellose, 40% showed rapid drug release. The release was found to follow the first order kinetics. The dissolution rate of tablet formulations was found to release the drug at a faster rate than the tablets prepared with plain drug. The drug excipients compatibility was confirmed by Fourier transform infrared and X-ray diffraction studies. No significant changes were observed from these studies.

**Key words:** Croscarmellose sodium, crospovidone, orodispensible tablets, stevia, zolmitriptan

INTRODUCTION

There has been an enhanced demand for more patient-friendly and compliant dosage forms in the present day market. As a result, the demand for developing new technologies has been increasing annually. For most therapeutic agents used to produce systemic effects, the oral route still represents the preferred way of administration, due to its several advantages and high patient compliance compared to many other routes. Drug dissolution and absorption, as well as the onset of clinical effect and drug bioavailability, may be significantly greater than those observed from conventional dosage forms. For the past few decades, researchers have been developing intraoral delivery systems that can produce desirable drug exposure for optimum therapeutic effect. As a result as evident from the abundance of scientific and patent literature over the last 20 years, nontraditional oral dosage forms (e.g., buccal, sublingual, periodontal, periodontal pocket, peribuccal, perilingual, tongue (i.e., lingual), and gum (i.e., gingival)).

Orodispensible tablets are also called as ODTs, quick disintegrating tablets, mouth dissolving tablets, fast disintegrating tablets, fast dissolving tablets, rapid dissolving tablets, porous tablets, and rapid melts. However, of all the above terms, United States pharmacopoeia (USP) approved these dosage forms as ODTs. The European Pharmacopoeia has used the term ODT for tablets that disperse readily within 3 min in the mouth before swallowing. The United States Food and Drug Administration defined ODT as “A solid dosage form containing a medicinal substance or active ingredient which disintegrates rapidly usually within a matter of seconds when placed on the tongue.” The disintegration time for ODTs generally ranges from several seconds to about a minute. ODTs are intended to disintegrate fast in the oral cavity include the following: Buccal, sublingual, periodontal, periodontal pocket, peribuccal, perilingual, tongue (i.e., lingual), and gum (i.e., gingival).

in the mouth to provide dispersion before being swallowed where the active ingredient is intended for gastrointestinal delivery and/or absorption. There is an intense search for low-calorie sweeteners and high potency to provide an alternative to sugar for its use in food and drugs. Stevia is a natural non-calorie sweetener obtained and extracted from the leaves of the plant species Stevia rebaudiana. The main active components of stevia are steviol glycosides (mainly stevioside and rebaudioside), which have up to 150 times the sweetness of sugar, are heat-stable, pH-stable, and not fermentable. These steviosides have a negligible effect on blood glucose, which makes stevia attractive to people on carbohydrate-controlled diets. Stevia’s taste has a slower onset and longer duration than that of sugar, and some of its extracts may have a bitter or licorice-like aftertaste at high concentrations.

A migraine is a severe, painful headache that is accompanied by sensory warning signs such as flashes of light, blind spots, tingling in the arms and legs, nausea, vomiting, and increased sensitivity to light and sound. The excruciating pain that migraines bring can last for hours or even days. Migraine treatment and prevention focus on avoiding triggers, controlling symptoms and taking medicines. Over-the-counter medications such as naproxen, ibuprofen, acetaminophen and other analgesics like aspirin with caffeine are often the first abortive therapies to eliminate a headache or substantially reduce pain. Zolmitriptan undergoes highly hepatic first pass metabolism and to solve the problems of hepatic first pass metabolism prepare sublingual tablets.

Zolmitriptan is a selective 5-hydroxytryptamine receptor subtype agonist indicated for the acute treatment of migraine attacks with or without aura in adults. Zolmitriptan is not intended for the prophylactic therapy of migraine or use in the management of hemiplegic or basilar migraine. Zolmitriptan is an agonist for a vascular 5-hydroxytryptamine receptor subtype (probably a member of the 5-HT ID family) having only a weak affinity for 5-HT1A, 5-HT5A, and 5-HT7 receptors and no significant affinity or pharmacological activity at 5-HT2, 5-HT3 or 5-HT4 receptor subtypes or at alpha-1, alpha-2, or beta-adrenergic, dopamine-1, dopamine-2; muscarinic, or benzodiazepine receptors. Zolmitriptan binds with high affinity to human 5-HT11 and 5-HT ID receptors leading to cranial blood vessel constriction.

In present investigation, an attempt has been made to enhance the solubility and dissolution rate of zolmitriptan by formulating it as orodispersible tablets employing superdisintegrants.

**MATERIALS AND METHODS**

Zolmitriptan A gift sample from Apotex Pharma Ltd., Bengaluru. Croscarmellose sodium (CCS) and crospovidone (CP), Kollidon VA64, were commercially produced from Yarrow Chem, Ltd., Mumbai. Magnesium stearate and mannitol were commercially produced from S.D. Fine Chem, Ltd., Mumbai.

**Saturated solubility studies**

Saturated solubility studies of zolmitriptan were performed in different dissolution media. An excess amount of lansoprazole was weighed and transferred into different conical flasks containing 10 ml of different dissolution media, that is, water, 6.8 pH, 7.2 pH phosphate buffer, 1.2 pH and were closed appropriately. All conical flasks were placed in the REMI incubator shaker. The shaker was allowed to operate at 50 rpm at 37°C ± 1°C for 24 h. Then, the conical flasks were removed from the incubator shaker, and the samples were filtered by using Whatman filter paper. The clear solution obtained by filtration was suitably diluted with appropriate dissolution media and the absorbance values were noted at 225 nm by using corresponding dissolution media as blank solutions.

**Preparation of zolmitriptan orodispersible tablets by direct compression**

Orodispersible tablets of zolmitriptan were prepared by direct compression with increasing the concentration ratios of croscarmellose and as a superdisintegrants were selected for the preparation of tablets. The ingredients were blended with super disintegrants such as CCS and CP, magnesium stearate and talc as lubricant and glidant. The powder blend was directly compressed into tablets using 10 station mini presses (ELITE). The compositions of various tablet formulations are given in Table 1.

**Evaluation of physical parameters for zolmitriptan orodispersible tablets**

The compressed tablets were further evaluated for their physical parameters such as weight uniformity, hardness, friability, and drug content.

**Dissolution studies on zolmitriptan orodispersible tablets**

Dissolution rate studies of zolmitriptan were performed in USP Apparatus Type II (paddle) as per the procedure described earlier. Based on the data obtained from the dissolution studies various parameters such as T₀, DE30% zero order, and first order release rate constants were estimated. The dissolution parameters such as T₀, and DE30% were measured directly from the dissolution profile curves as shown in Figure 1a and b.

**Characterization of orodispersible tablets**

Among the various tablet formulation prepared by using CCS and CP CCS showed rapid drug release when compared...

to CP and was further evaluated for the drug excipient compatibility by Fourier transform infrared (FTIR), X-ray diffraction (XRD) studies.

Fourier transforms infrared spectroscopy study

The FTIR spectra of zolmitriptan, superdisintegrants, and formulations were obtained using brucker FTIR spectrophotometer to study the interaction between drug and excipients in orodispersible tablets. The samples were prepared in KBr discs (2 mg sample in 200 mg KBr) and the sampling range was 400-4000 cm⁻¹ and the resolution was 4 cm⁻¹. The FTIR spectra are shown in Figure 2a and b.

X-ray diffraction study

Powder XRD (PXRD) patterns were tracted employing X-ray Diffractometer Burkser AXS, DH Advances, Germany for all the samples using Ni filetr, CuK (6) radiation, a voltage of kV, a current of 20 mA and receiving slit of 0.2. The samples were analyzed over 20 range of 5° to 60°, with scan step size of 0.020° (2θ) and scan step time of 1 s. The XRD spectra are shown in Figure 3a and b.

RESULTS AND DISCUSSION

Saturated solubility studies revealed that zolmitriptan show maximum solubility in 6.8 pH phosphate buffer medium than the other medium used. The drug concentration was measured at an absorption maximum of 225 nm using ultraviolet spectrophotometer (ELICO SL120) for all dissolution medium. The compositions of various tablets prepared were shown in Table 1. All the orodispersible tablets were compressed under identical conditions to avoid processing variables. The physical parameters such as weight uniformity, hardness, friability, and drug content, were evaluated for all the tablets prepared. The physical parameters evaluated were highly uninformed and all tablets were found to be within the I.P. specified limits. The weight uniformity values were in the range of 198 ± 3.0 to 200 ± 10 mg, hardness was found to be 3.5 ± 0.4 kg/cm², friability values were in the range 0.1-0.8% and drug content values were in the range of 29.98 ± 0.2 mg/tablet for the zolmitriptan ODT formulations. The dissolution studies on zolmitriptan marketed tablet, and all the tablet formulations were performed by using 6.8 pH phosphate buffer using paddle method. The dissolution rate of the tablet formulations was found to be rapid when compared to marketed tablet of zolmitriptan (zolmig 5 mg.). Among the tablets prepared tablets with the CCS as superdisintegrants in the concentration of 40% tend to exhibit rapid dissolution than all the formulations. The rate of rapid drug release is in the order of CCS > CP in the tablet formulations for superdisintegrants. Among the various tablet formulations F6 shows rapid drug release (up to 99.8%) when compared to marketed formulation (84.89%). This can be attributed improved wettability and dispersibility as well as increased amorphous fraction of drug. It was also found that as the concentration of superdisintegrants increases,
the tablets undergo rapid dissolution and drug release. This may be due to rapid intake of water by superdisintegrants, which leads to the faster dissolution of the tablets and showed the improved dissolution profiles of poorly soluble zolmitriptan. The *in vitro* dissolution parameters were given in Table 2.

The formulations, which showed good *in vitro* performance, were subjected to accelerated stability studies. The formulation F6 was subjected to accelerated stability studies. It was also observed that there was no significant change in drug release from the tablet formulations. Thus, the drug release characteristics of zolmitriptan ODTs designed were found to be stable.

CONCLUSION

The present study has shown that it is possible to increase the dissolution rate of poorly soluble drug zolmitriptan by preparing it as orodispersible tablets using various superdisintegrants shows the rapid dissolution and drug release when compared with marketed tablets. Based on the study, it may be concluded that zolmitriptan tablets prepared using CCS as superdisintegrant was found to be ideal for rapid dissolution rate, which, in turn, increases the bioavailability.

ACKNOWLEDGMENTS

The authors express their gratitude to Apotex pharma Ltd., Bangalore for providing the gift samples. The authors are thankful to the management of Chebrolu Hanumaiah Institute of Pharmaceutical Sciences, Guntur for providing the facilities to carry out the research work.
